White Box Testing:

White box testing is a testing method where the tester can see and test the internal code and structure of the program. Here the tester understands the program logic, source code, conditional loops and internal data flow. This testing is performed by the developers. They check every statement of the code, run loops and data flow correctly inside the program. This testing is needed because it helps to detect internal coding errors early in the development process.

Advantages: Finds coding errors early; Improves code quality; Easier debugging.

Problems: Require programming knowledge; Time consuming for large system; may miss missing features.

Example:

if $\text{age} \geq 18$; then it's a valid user
here, developer checks the internal code to see if all conditions are working correctly.

Black box Testing

It is a testing method where the tester does not see the internal code. The tester only checks the inputs given by to the system and outputs produced by the system. The internal program logic is done by the tester. This testing is important because it checks whether the system work correctly from the users perspective. This testing ensure that the system meets user requirements and expectations.

Advantages: Here, no need programming knowledge, Test from the user perspective, good for large system, helps to find missing features.

problems: limited coverage of code, here tester can not see internal code that why code errors may remain hidden, difficult to identify the cause of errors, need many many test cases.

Example:

Input: username: u-123
password: 123

output: login successful.
